AI now helps write the software that runs machines. No mainstream language can prove what that software will never do.

Batteries, flywheels and flight controls run on code that is tested, reviewed, and then trusted.

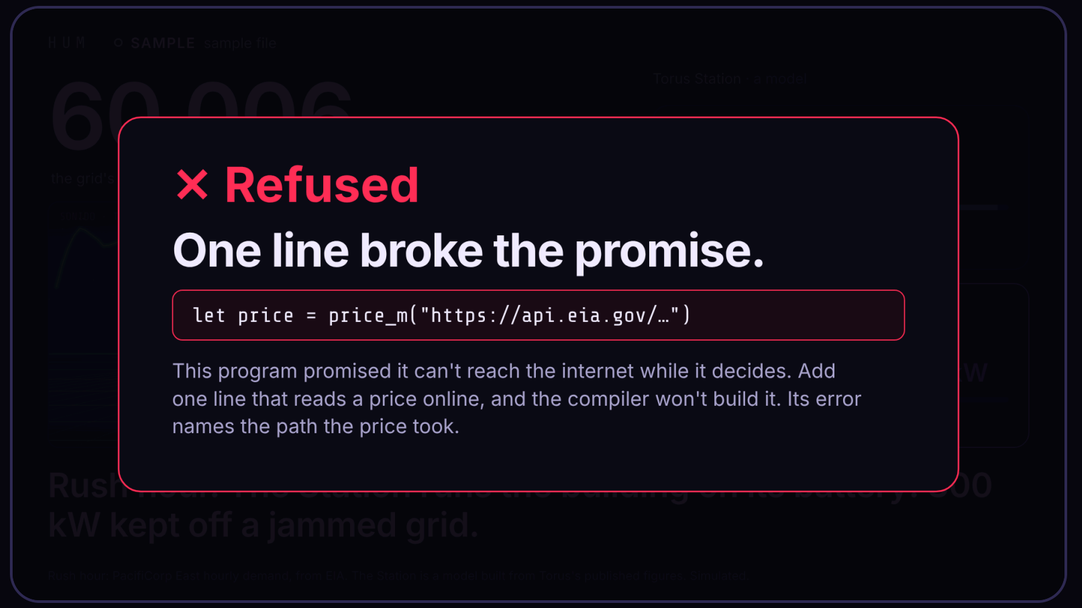

Mentl is a programming language whose compiler proves it.

Mentl proves what software can never do.

You write a promise into the code, such as "this never touches the internet" or "this never asks for more than 100 kW".

The compiler checks the promise through every function the code calls. **Break it, and the program won't build.**

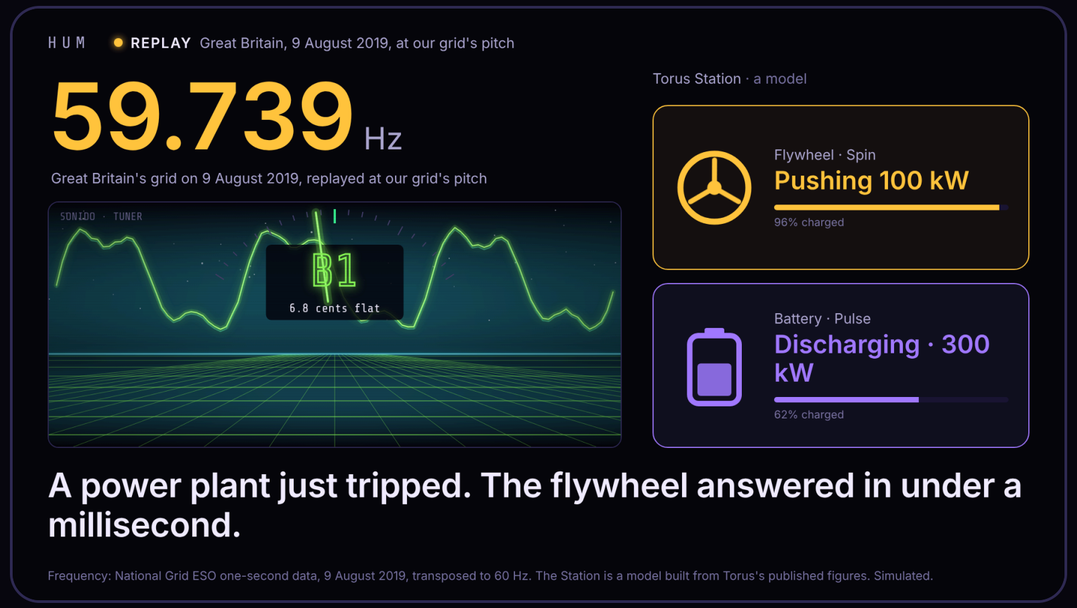

Seven months and 2,600 commits since March. The compiler is written in Mentl and compiles itself. Open source.

Show it working

Built this week: software that hears the power grid.

- **A guitar pickup hears the grid** in any room's wiring, to a thousandth of a hertz, measured by my audio library, sonido.
- **A model of a Torus Station decides** what to do in under a millisecond, with software written in Mentl.
- **That software is proven** unable to reach the internet while it decides.

Before Monday 4 PM: the language, 2,610 commits since March 15, and sonido, 461 commits since January 25. Since then: everything on this slide.

Who needs it in Utah

TORUS · SALT LAKE CITY

Builds flywheel-and-battery Stations that steady the grid. The software inside each Station is the first place a proof pays. Torus's judge is seeing this demo today.

HILL AFB · 309TH SOFTWARE ENGINEERING GROUP

Maintains flight software for the F-16, the F-35 and the missile fleet, where every claim about the software needs evidence.

First conversation: Torus engineering, this month.
First hires: a controls engineer and a compiler engineer, in Salt Lake City.

What $10,000 unlocks

$10,000 puts a proven controller on a real machine in Utah within ninety days.

Day 30 Form the Utah company. Run the controller on a battery inverter on my bench.

Day 60 Run it beside a real battery at one Utah site.

Day 90 A pilot agreement with that site, and an SBIR proposal with Nucleus Grow.

$7,000 for the inverter and battery bench. **$3,000** to form the company, register for federal grants and install at the site.

Two asks. A Utah operator who will host it. An introduction to Hill AFB's 309th.

BACKUP

What is proven, exactly

THE CONTROLLER'S PROMISE	STATUS
No network, file, clock or other host call while it decides	Proven by the compiler through every call
No memory allocated while it decides	Proven
The flywheel within 100 kW, the battery within 300 kW	Clamped in code; the audit lists open claims in eight functions
It never crashes	Not claimed; the compiler says it can
Its decisions are good	Tested on recordings, not proven

The compiler is written in Mentl, and the pinned binary rebuilds itself byte for byte. A claim it cannot decide is listed as open, never passed as proven.

BACKUP

From the laptop to the pedal: the day-30 engineering

WHAT STANDS IN THE WAY	MEASURED TODAY	THE FIX
No WebAssembly engine on the pedal's chip	The controller is a 37 KB WebAssembly file	Embed an interpreter written in Rust, or compile the file to C
Built for threads	Shared memory and atomic instructions	A single-threaded build; the controller uses no threads
Memory	The reading loop keeps 8 KB per reading	A reading loop that allocates nothing
Speed	About 291,000 instructions per reading	Pass numbers instead of text

The decision itself already allocates nothing. The work is in the loop around it and in the engine on the chip.
